2004/8/22

Abstract
We construct a family of self-repelling and self-attracting walks (stochastic chains) on the (infinite) pre-Sierpiński gasket. The family continuously interpolates the simple random walk and a self-avoiding walk. The asymptotic behavior of the walks is given in terms of the displacement exponent.

MSC 2000 subject classifications: Primary 60G17; secondary 82C41.

Key words: self-repelling walk, self-avoiding walk, self-attracting walk, Sierpinski gasket, displacement exponent, mean-square displacement

1 Introduction.

In [3] Ben Hambly and the authors considered a family of self-repelling walks with fixed endpoints on the finite pre-Sierpiński gaskets. We proved the existence of the continuum limit, i.e., reducing the unit length to 0 (with suitable scaling of time parameter). The limit is a family of continuous self-repelling processes with specific fixed endpoints (‘pinned processes’). We studied their sample path properties, such as Hölder continuity, short-time speed and a generalized law of the iterated logarithm.

In this paper, we consider the same family of walks on the finite pre-Sierpiński gaskets, which we recall in Section 2, but instead of taking continuum limit, we fix the unit length and extend the walks to the (infinite) pre-Sierpiński gasket, thus remove the pinning condition and construct (infinite length) stochastic chains, and study their properties.

In Section 3 (Theorem 5) we construct a family of stochastic chains on the pre-Sierpiński gasket consistent with the pinned self-repelling walks on the finite pre-Sierpiński gaskets studied in [3]. Our family of walks is parametrized by $u$ which indicates the strength of self-repulsion. The walk corresponding to $u = 1$ is the standard simple random walk, and for $u = 0$ the corresponding walk is self-avoiding and of infinite length. The path measure for the self-avoiding ($u = 0$) case is rather complex, as is for all cases other than the simple random walk ($u \neq 1$). In particular, it is supported on walks without sharp turns for $u = 0$. The measure is natural, however, from the renormalization group point of view [4], in that it corresponds to the unique fixed point of the renormalization group recursion equation (10) associated with the self-avoiding walks on the pre-Sierpiński gasket which respect symmetries of the Sierpiński gasket. This family of walks on the finite pre-Sierpiński gaskets parametrized by $u$ is introduced in [3] to interpolate the simple random walk and the measure on self-avoiding paths by the path measures corresponding to the fixed points of the ($u$ dependent) renormalization group, which, hereafter we refer to as the fixed point theories. (We can of
course consider more general class of walks by introducing more parameters, but to make clear the aim of this paper, we will stick to the family studied in [3].) We can also construct the walks for \( u > 1 \), which correspond to self-attracting walks.

It may also be worthwhile to note that the extension of pinned walks to the infinite pre-Sierpiński gasket is not trivial for the walks. The continuum limit continuous processes of [3] have exact self-similarities which can be used to obtain extensions to large scales. The walk (chain), on the other hand, has a finite unit, so that there is no exact self-similarity. It turns out, as we see in Section 3, that the fixed point condition of the renormalization group serves as a consistency condition in applying the extension theorems. In this sense, we may say that the renormalization group fixed point theory is an extended notion of a self-similar processes. Note also that since our family of walks lack Markov properties, constructions based on analytic approach cannot be applied in general.

In Section 4, we prove in Theorem 8 an asymptotic behavior of the self-repelling and self-attracting walks, in terms of the \( (u \) dependent) displacement exponent \( \gamma \). (The exponent is equal to the exponent for the ‘mean-square displacement’ in physics literatures, defined by \( E[(w(n))^2] \sim n^{2\gamma} \). Our proof implies that the exponent is the same for all the moments \( E[(w(n))^s] \sim n^{s\gamma} \), \( s > 0 \).

Main tools for the proof are a reflection principle and an estimate on short and long paths. These tools have also been employed in [6], where we proved the existence of displacement exponent for a self-avoiding walk. We would like to emphasize that the reflection principle introduced in [6] is similar in spirit to the reflection principle used in Section 4 but is actually entirely different. In fact, by comparing the definition of reflection principles in [6] and that in this paper for the self-avoiding \( (u = 0) \) case, one should notice that they are absolutely different reflections. A main reason for the difference is that, in [6] we considered equal weights for self-avoiding walks with a fixed number of steps, hence in applying a reflection principle we only needed to compare the numbers of certain sets of walks and their reflections, whereas we here consider fixed point theories, whose weights are natural from renormalization point of view but complex from walks’ point of view and also depends on \( u \), so that a very delicate coupling type argument is necessary. On the other hand, since we are working on fixed point theories, the estimates on short and long paths are considerably easier than those in [6].

Acknowledgements. The authors would like to thank the referee for careful reading of the manuscript.

2 Self-repelling walks on the finite pre-Sierpiński gasket.

The pre-Sierpiński gasket is defined as follows. Let \( O = (0, 0) \), \( a_0 = (\frac{1}{2}, \frac{\sqrt{2}}{2}) \), \( b_0 = (1, 0) \), \( c_0 = (1, 0) \), \( d_0 = (0, \frac{\sqrt{2}}{2}) \), and \( a_N = 2^N a_0 \), \( b_N = 2^N b_0 \), \( c_N = 2^N c_0 \), \( d_N = 2^N d_0 \), \( N \in \mathbb{N} \). Let \( F_N^u \) be the set of all the points on the vertices and edges of \( \triangle Oa_0b_0 \). We define a sequence of sets \( F_0^u, F_1^u, F_2^u, \ldots \), inductively by

\[
F_{N+1}^u = F_N^u \cup (F_N^u + a_N) \cup (F_N^u + b_N), \quad N \in \mathbb{Z}_+, \quad \{0, 1, 2, \ldots \},
\]

where \( A + a = \{x + a : x \in A\} \) and \( kA = \{kx : x \in A\} \). Let \( F_N^u = F_N^u \cup (F_N^u + c_N) \) and \( F_0 = \bigcup_{N=1}^{\infty} F_N^u \).

We call \( F_0 \) the (infinite) pre-Sierpiński gasket. For \( N \in \mathbb{Z}_+ \), let \( F_N = 2^N F_0 \) and denote the set of vertices in \( F_N \) by \( G_N \).

For \( n \in \mathbb{Z}_+ \) we call \( w = (w(0), w(1), \ldots, w(n)) \) an \( n \)-step path (or a path of length \( n \)), if \( w(i) \in G_0 \), \( |w(i+1) - w(i)| = 1 \), \( w(i)w(i+1) \in F_0 \), \( i = 0, 1, \ldots, n - 1 \).

Similarly, we call \( w = (w(0), w(1), w(2), \ldots) \) an infinite path (or a path of infinite length), if \( w(i) \in G_0 \), \( |w(i+1) - w(i)| = 1 \), \( w(i)w(i+1) \in F_0 \), \( i = 0, 1, 2, \ldots \).

We denote the length of path \( w \) by \( L(w) \).
For a path \( w \) and \( A \subset F_0 \), we define the hitting time \( T_A(w) \) of \( A \) for \( w \), by \( T_A(w) = \min \{ j \geq 0 : w(j) \in A \} \). If the minimum does not exist, we put \( T_A(w) = \infty \). For a path \( w \) on \( F_0 \) and \( M \in \mathbb{Z}_+ \), define \( T^M(w) \), \( i = 0, 1, 2, \ldots \), by induction as follows: \( T^M_0(w) = T_{G_M}(w) \), and for \( i \geq 1 \), let \( T^M_i(w) = \min \{ j > T^M_{i-1}(w) : w(j) \in G_M \cup \{ w(T^M_{i-1}(w)) \} \} \), if the minimum exists, otherwise \( T^M_i(w) = \infty \). \( T_i(w) \) is the time when the path \( w \) hits a vertex of \( G_M \) for the \( i+1 \)-th time (including the case \( i = 0 \)), under the condition that if \( w \) hits the same element of \( G_M \) more than once in a row, we consider it as once.

We mainly consider walks starting at the origin. (Notion for general paths introduced so far are also used when we consider cutting and reflecting procedures of paths in the proofs of our results.) For each \( n \in \mathbb{Z}_+ \), denote a set of \( n \)-step paths on \( F_0 \) starting at the origin \( O \) by \( W(n) \). Namely,

\[
W(n) = \{ (w(0), w(1), \ldots, w(n)) : w(0) = O, w(i) \in G_0, |w(i+1) - w(i)| = 1, w(i)w(i+1) \in F_0, i, i+1 \in \{0, 1, \ldots, n \} \}.
\]

For \( w \in W(n) \), \( L(w) = n \). Let \( W^* = \bigcup_{n=1}^{\infty} W(n) \).

Fix \( N \in \mathbb{Z}_+ \) for the rest of this section. Let \( A_N = \{ a_N, b_N, c_N, d_N \} \), and define \( W_{N,a} = \{ w \in W^* : L(w) = T_{A_N} = T_{\{a_N\}} \} \), \( W_{N,b} = \{ w \in W^* : L(w) = T_{A_N} = T_{\{b_N\}} \} \), \( W_{N,c} = \{ w \in W^* : L(w) = T_{A_N} = T_{\{c_N\}} \} \), \( W_{N,d} = \{ w \in W^* : L(w) = T_{A_N} = T_{\{d_N\}} \} \), and \( W_N = W_{N,a} \cup W_{N,b} \cup W_{N,c} \cup W_{N,d} \).

For a path \( w \in W_N \) and \( M \in \mathbb{Z}_+ \), define a ‘decimation’ map \( Q_M \) by setting \( (Q_Mw)(i) = w(T^M_i(w)) \) for \( i = 0, 1, 2, \ldots, j \), where \( j \) is the smallest integer such that \( T^M_{j+1}(w) = \infty \). \( Q_Mw \) may be regarded as a path on \( F_0 \). If we write \( (2^{-M}Q_Mw)(i) = 2^{-M}w(T^M_i(w)) \), then \( 2^{-M}Q_Mw \) is a path on \( F_0 \) and \( L(2^{-M}Q_Mw) = j \). We will write \( L(Q_Mw) = L(2^{-M}Q_Mw) \) for the length of decimated path (with a unit step normalized to be 1), and \( T^N_i(Q_Mw) = T^N_i(2^{-M}Q_Mw) \) for the hitting times.

For a path \( w \in W_N \), define the reversing number \( N_K(w) \) and the returning number \( M_K(w) \) for level \( K \in \{0, 1, \ldots, N-1\} \) in the following manner. For \( \ell = 1, \ldots, L(Q_{K+1}w) \), let

\[
N_K(\ell)(w) = \sharp \{ i \in \mathbb{Z}_+ : T_{\ell-1}^{K+1}(Q_Kw) < i < T_{\ell}^{K+1}(Q_Kw) : (Q_Kw)(i-1)(Q_Kw)(i)(Q_Kw)(i+1) < 0, (Q_Kw)(i) \neq (Q_Kw)(T_{\ell-1}^{K+1}(Q_Kw)) \},
\]

(1)

where \( \bar{a} \cdot \bar{b} \) denotes the inner product of \( \bar{a} \) and \( \bar{b} \) in \( \mathbb{R}^2 \), and

\[
M_K(\ell)(w) = \sum_{\ell=1}^{L(Q_{K+1}w)} N_K(\ell)(w),
\]

\[
M_K(w) = \sum_{\ell=1}^{L(Q_{K+1}w)} M_K(\ell)(w).
\]

Thus \( N_K(w) \) counts the number of times the path \( Q_Kw \) makes U-turns or sharp-angle turns at vertices in \( G_K \setminus G_{K+1} \), and \( M_K(w) \) counts the number of times \( Q_Kw \) revisits a vertex in \( G_{K+1} \). It is these types of steps that we will suppress or enhance in our path measures.

For \( p, q \in \{a, b, c, d\} \), we define bijections \( R_{p,q} : W_{N,p} \to W_{N,q} \) as follows. \( R_{a,d}, R_{d,a}, R_{b,c}, \) and \( R_{c,b} \) are defined as the reflection with regard to y-axis. Consider the reflection of the parts of path within \( \Delta O a, b N \) with regard to the line \( y = \frac{1}{\sqrt{3}}x \), and that of the parts within \( \Delta O c, d N \) with regard to the line \( y = -\frac{1}{\sqrt{3}}x \). This defines \( R_{a,b}, R_{b,a}, R_{c,d}, \) and \( R_{d,c} \). Then \( R_{a,c} = R_{c,e} \circ R_{a,b} \) defines \( R_{a,c} \), and other cases are defined in a similar way. Under these bijections, \( N_K(w), M_K(w) \) and \( L(w) \) remain invariant.

Let \( x > 0 \) and \( u \geq 0 \). For \( w \in W_N \), define

\[
f_N(u, w) = f_N(w) = \prod_{K=0}^{N-1} u^{N_K(w)+M_K(w)},
\]

(3)
Proof.

(1) For each \( M < N \), there is a natural one-to-one mapping \( \Psi \) and \( \Phi \), respectively. Conversely, given arbitrarily \( w' \in W_{N,a} \), any \( \bar{w} \in W_{N,a} \) can be the \( j \)-th path segment (5) of some \( w \in W_{N+1,a} \) such that \( 2^{-N}Q_{NW} = w' \). Thus there is a one-to-one correspondence \( w_j \mapsto \bar{w}_j \in W_{N,a} \). With this correspondence, there is a natural one-to-one mapping

\[
W_{N+1,a} \ni w \mapsto (w', \bar{w}_1, \bar{w}_2, \cdots, \bar{w}_{L(w')}) \in W_{1,a} \times W_{N,a} \times \cdots \times W_{N,a}.
\]

Also we have

\[
L(\bar{w}_j) = T_j^N(w) - T_{j-1}^N(w),
\]

and

\[
L(w) = \sum_{j=1}^{L(2^{-N}Q_{NW})} (T_j^N(w) - T_{j-1}^N(w)) = \sum_{j=1}^{L(w')} L(\bar{w}_j).
\]

For any \( w \in W_{N+1,a} \), by considering the path decomposition \( (w', \bar{w}_1, \bar{w}_2, \cdots, \bar{w}_{L(w')}) \) determined by the correspondence (6), we have from (3)

\[
f_{N+1}(w) = f_1(w') \prod_{j=1}^{L(w')} f_N(\bar{w}_j).
\]

Combining (3), (4), (8) and (9), we have the recursion relation of \( \Phi_N \),

\[
\Phi_{N+1}(x, u) = \Phi(\Phi_N(x, u), u) = \Phi \circ \cdots \circ \Phi(x, u).
\]

This implies that for any \( M < N \),

\[
\Phi_N(x, u) = \Phi_{N-M}(\Phi_M(x, u), u).
\]

Let \( r_u \) be the radius of convergence for \( \Phi(x, u) \) as a power series in \( x \).

**Proposition 1**

(1) For each \( u \geq 0 \), \( r_u > 0 \) and there is a unique fixed point \( x_u \) of the mapping \( \Phi(\cdot, u) : (0, r_u) \to (0, \infty) \), that is, \( \Phi(x_u, u) = x_u, x_u > 0 \). As a function in \( u \), \( x_u \) is continuous and strictly decreasing on \([0, 1] \).

(2) Let \( \lambda_u = \frac{\partial \Phi}{\partial x}(x_u, u) \). Then \( \lambda_u \) is continuous in \( u \) and \( \lambda_u > 2 \).

**Proof.** The case of \( 0 \leq u \leq 1 \) corresponds to Proposition 2.3 in [3]. For \( u > 1 \), it is sufficient to show \( r_u > 0 \). The rest follows just as in the case of \( 0 \leq u \leq 1 \). Note that from the definitions of \( N_0(w) \) and \( M_0(w) \), we have \( L(w) \geq N_0(w) + M_0(w) \). Thus if \( u > 1 \),

\[
\Phi(x, u) = \sum_{w \in W_{1,a}} u^{N_0(w)+M_0(w)} x^{L(w)} \leq \sum_{w \in W_{1,a}} (ux)^{L(w)} = \Phi(ux, 1).
\]

Since we already know that \( r_1 > 0 \), we have \( r_u \geq r_1/u > 0 \). \( \square \)
consisting of infinite-length paths whose first n steps are identical to w.

(10) implies that \( \Phi_N(x_u, u) = x_u \) for all \( N \in \mathbb{N} \). In the two extreme cases, we know that \( x_0 = \frac{\sqrt{5} - 1}{2} \), \( \lambda_0 = \frac{7 - \sqrt{5}}{2} \) (see [4, 6]), and \( x_1 = \frac{1}{4}, \lambda_1 = 5 \) (see [1, 7]).

We next define a probability measure \( P_{N,a}^w \) on \( W_{N,a} \) by assigning to each \( w \in W_{N,a} \),

\[
(12) \quad P_{N,a}^w[\{w\}] = \left( \prod_{k=0}^{N-1} u_{K(k)+M(k)}^{L(w)} / \Phi_N(x_u, u) \right) = f_N(w)x_u^{L(w)-1}
\]

\( P_{N,a}^w \) corresponds to the simple random walk on \( F_N \) conditioned that \( T_{\lambda_N} = T_{(a_N)} \). Under \( P_{N,a}^0 \), only self-avoiding paths survive. (To be precise, the measure corresponds to the fixed point of the renormalization group [4], hence the measure is supported on the self-avoiding paths with no sharp turns.) Let us denote \( \lambda \) the law of \( P_{N,a}^0 \) by assigning to each \( w \in W_{N,a} \),

\[
E_N[\Phi_N(x_u, u)] = \frac{1}{x_u} \Phi_M(x_u, u), \quad t \geq 0.
\]

Proposition 2 If \( w \in W_{N,a} \) and \( M \leq N \), then \( 2^{-M}Q_{M} w \in W_{N-M,a} \) and \( Q_{M} P_{N,a}^w = P_{N-M,a}^w \).

For \( M \in \mathbb{Z}_+ \) and \( k \in \mathbb{N} \), put \( S_k^M = T_k^M - T_{k-1} \).

Proposition 3 Assume \( N \geq M \) and \( k \in \mathbb{N} \).

(a) Let \( w \in W_{N,a} \). Under the conditional probability \( P_{N,a}^w[\cdot | S_k^M(w)] < \infty \), the random variables \( S_k^M(w) \) for \( i = 1, \ldots, k \) are i.i.d. and they are jointly independent of \( Q_{M} w \).

(b) The law of \( S_k^M \) under \( P_{N,a}^w \) is equal to that of \( S_k^M \) under \( P_{M}^w \). \( E_M[S_k^1] = \lambda_u^M \) and the Laplace transform of \( S_k^1 \) is given by \( g_u^M(t) = E_M[e^{-tS_k^1}] = \frac{1}{x_u} \Phi_M(x_u e^{-t}, u), \quad t \geq 0 \).

Proposition 4 The law of \( \lambda_u^N S_k^N \) under \( P_{N,a}^w \) converges weakly as \( N \to \infty \) to that of a random variable \( S^* \), with properties \( P_u[S^* > 0] = 1 \), \( E_u[S^*] = 1 \), and its Laplace transform \( g_u(t) = E^u[\exp(-tS^*)] \) being the unique solution to \( g_u(\lambda_u t) = \frac{1}{x_u} \Phi(x_u g_u(t), u), \quad g'_u(0) = 1 \).

3 Existence of stochastic chain consistent with the renormalization group.

Let \( N \in \mathbb{N} \). The probability measure \( P_N^w \) in the preceding section is defined on the set \( W_{N,a} \), which is a set of paths on \( F_N \) with fixed endpoints \( \sigma \) and \( a_N \). In deducing displacement exponents, we need to consider probability measures on sets of paths with fixed length (steps) \( n \) for all \( n \in \mathbb{N} \). We prove the existence of a probability measure \( P_n \) on the set of paths of infinite length, for which the probability of the paths up to the first hitting time of \( A_N \) coincides with \( P_N^w \) (The precise statement is given in Corollary 7).

Let \( P_{N,a}^w \) be a probability measure on \( W_N \) such that \( P_{N,a}^w[A] = P_{N} [A] \) for any \( A \subset W_{N,a} \), and define probability measures \( P_{N,b}^w, P_{N,c}^w, P_{N,d}^w \) on \( W_N \) supported on \( W_{N,b}, W_{N,c}, W_{N,d} \), by the same formula as (12), with \( a_N \) replaced by \( b_N, c_N, d_N \), respectively. Define

\[
W(\infty) = \{ (w(0), w(1), w(2), \cdots) : w(0) = O, \ w(i) \in G_0, |w(i+1) - w(i)| = 1, \\
\quad w(0)w(i+1) \in F_0, \ i \in \mathbb{Z}_+ \},
\]

and let \( F \) be the \( \sigma \)-algebra on \( W(\infty) \) generated by cylinder sets

\[
C_n(w) = \{ w' = (w'(0), w'(1), w'(2), \cdots) \in W(\infty) : w'(j) = w(j) , \ j = 0, 1, 2, \cdots, n \}, \quad w \in W(n), \quad n \in \mathbb{N},
\]

consisting of infinite-length paths whose first \( n \) steps are identical to \( w \).
Theorem 5 There exists a probability measure $P^u$ on $(W(\infty), \mathcal{F})$ satisfying the following: For each $n \in \mathbb{N}$ and $w = (w(0), w(1), w(2), \cdots, w(n)) \in W(n)$, it holds that

$$P^u[w' \in W(\infty) : w'(j) = w(j), \ j = 0, 1, 2, \cdots, n] \quad \text{(14)}$$

for any integer $N$ satisfying

$$|w(j)| < 2^N, \ j = 0, 1, 2, \cdots, n - 1,$$

where $| \cdot |$ denotes the Euclidean metric.

We remark that $2^N$ or more steps are required for a path starting from $O$ to hit $A_N = \{a_N, b_N, c_N, d_N\}$, hence the condition (15) holds if $2^N \geq n$. Also, for each $j \in \mathbb{Z}_+$, $X(j, \cdot) : W(\infty) \to G_0$ defined by $X(j, w) = w(j)$ is a $G_0$-valued stochastic variable on $(W(\infty), \mathcal{F}, P^u)$.

To prove Theorem 5, we first note the following. For a path in $W_{N+1}$, the first hit of $G_N \setminus \{O\}$ occurs at one of $A_N$. By restricting the original path to $[0, T_{A_N}]$, we have a correspondence $W_{N+1} \to W_N$.

In Section 2, we introduced natural bijections $R_{p,q} : W_{N,p} \to W_{N,q}, \ p, q \in \{a, b, c, d\}$ which maps $w \in W_{N,p}$ to $R_{p,q}w \in W_{N,q}$ in such a way that its shape (modulo partial reflection) does not change, and in particular,

$$f_N(w) = f_N(R_{p,q}(w)).$$

For simplicity of notation, we may write $R_{p,q}$ for an identity map, and, in the proof of Theorem 5, we will fix $u$ and write $P_{N,q}$ for $P_{N,p}^u$.

Proposition 6 Let $N$ be a positive integer and let $p \in \{a, b, c, d\}$. Consider a path

$$\hat{w} = (\hat{w}(0), \hat{w}(1), \hat{w}(2), \cdots, \hat{w}(L(\hat{w}))) \in W_{N,p}.$$ 

Then for any integer $N' > N$,

$$\sum_{q \in \{a, b, c, d\}} P_{N',q}[\{w \in W_{N',q} : w(j) = \hat{w}(j), \ j = 0, 1, 2, \cdots, L(\hat{w})\}] = P_{N,p}[\{\hat{w}\}].$$

Proof. We prove the case $N' = N + 1$: The general case follows by induction in $N'$. We also assume $\hat{w} \in W_{N,a}$, since other cases are similar.

We decompose $w \in W_{N+1,q}$ into $(w', \tilde{w}_1, \cdots, \tilde{w}_{L(w')}) \in W_{1,q} \times W_{N,a} \times \cdots \times W_{N,a}$, in the same way as in (6), where $w' = 2^{-N}Q_{N,w'}$ and $\tilde{w}_j$ is the $j$-th path segment identified, via appropriate reflection, with a path in $W_{N,a}$. Using (12), (8), (9) and (16), for the first equality, the condition that $w(j) = \hat{w}(j), \ j = 0, 1, 2, \cdots, L(\hat{w})$ for the second, (4) for the third, and finally, $\Phi_N(x_u, u) = x_u$ and $\tilde{w}(L(\tilde{w})) = a_N$, we have,

$$P_{N+1,q}[\{w \in W_{N+1,q} : w(j) = \hat{w}(j), \ j = 0, 1, 2, \cdots, L(\hat{w})\}]$$

$$= \sum_{w' \in W_{1,q}} f_1(w') \prod_{j=1}^{L(w')} f_N(\tilde{w}_j) \prod_{j=1}^{L(\hat{w})} x_u^{-1}(\hat{w}_j)$$

$$= \sum_{w' \in W_{1,q}} f_1(w') \prod_{j=1}^{L(w')} f_N(\tilde{w}_j) x_u^{L(\hat{w})}$$

$$= f_N(\tilde{w}) x_u^{L(\tilde{w})} \sum_{w' \in W_{1,q}} f_1(w') \prod_{j=2}^{L(w')} f_N(\tilde{w}_j) x_u^{L(\tilde{w})}$$

$$= f_N(\tilde{w}) x_u^{L(\tilde{w})} \prod_{j=2}^{L(w')} f_1(w') \Phi_N(x_u, u) x_u^{L(w')-1}$$

$$= f_N(x_u) x_u^{L(w)} \prod_{j=2}^{L(w')} f_1(w') x_u^{L(w')-1}.$$
Hence we have
\[
\sum_{q \in \{a, b, c, d\}} P_{N+1,q} \{ w \in W_{N+1,q} : w(j) = \bar{w}(j), \ j = 0, 1, 2, \cdots, L(\bar{w}) \} = f_N(\bar{w}) x_u^{L(\bar{w}) - 1} \sum_{q \in \{a, b, c, d\}} \sum_{w' \in W_{1,a} : w'(1) = a_0} f_1(w') x_u^{L(w') - 1}.
\]
According to the definition of $R_{p,q}$, $w' \in W_{1,q}$ is mapped by $R_{q,a} : R_{q,a}(w') \in W_{1,a}$, while if $w'(1) = a_0$ then this point is mapped to $R_{q,a}(w')(1) = q_0$. On the other hand, $L(w') = L(R_{q,a}(w'))$, and (16) implies $f_N(w') = f_N(R_{q,a}(w'))$. Note also that the first step $w'(1)$ is a point in $A_0$. Therefore
\[
f_N(\bar{w}) x_u^{L(\bar{w}) - 1} \sum_{q \in \{a, b, c, d\}} \sum_{w' \in W_{1,a} : w'(1) = a_0} f_1(w') x_u^{L(w') - 1} = f_N(\bar{w}) x_u^{L(\bar{w}) - 1} \sum_{w' \in W_{1,a} : w'(1) = q_0} f_1(w') x_u^{L(w') - 1} = P_{N,p}[\{ \bar{w} \}].
\]

\[\square\]

**Proof of Theorem 5.** Let $n \in N$. Take an $n$ step path $w \in W(n)$ and a cylinder set $C_n(w)$ defined in (13). Take $N$ satisfying (15), and put
\[
(17) \quad \tilde{P}_n[C_n(w)] = \frac{1}{4} \sum_{p \in \{a, b, c, d\}} P_{N,p}[\{ w' \in W_{N,p} : w'(j) = w(j), \ j = 0, 1, 2, \cdots, n \}].
\]
We first prove that the right-hand side is independent of $N$. Let $N' > N$. For any $w' \in W_{N'}$, it holds that $T_{1,N}'(w') < T_{1,N}(w')$. By restricting $w'$ up to $T_{1,N}'(w')$, we have a path in $W_N$. Since (15) implies $n \leq T_{1,N}'(w')$, we can classify the paths in $\{ w' \in W_{N',p} : w'(j) = w(j), \ j = 0, 1, 2, \cdots, n \}$ by the behavior up to $T_{1,N}'(w')$ and we have
\[
\frac{1}{4} \sum_{q \in \{a, b, c, d\}} P_{N',q}[\{ w' \in W_{N',q} : w'(j) = w(j), \ j = 0, 1, 2, \cdots, n \}]
= \frac{1}{4} \sum_{p \in \{a, b, c, d\}} \sum_{\tilde{w} : w(j) = w(j), \ j = 0, 1, 2, \cdots, n} P_{N',q}[\{ w' \in W_{N',q} : w'(j) = \tilde{w}(j), \ j = 0, 1, 2, \cdots, L(\tilde{w}) \}],
\]
which, by Proposition 6, is equal to
\[
\frac{1}{4} \sum_{p \in \{a, b, c, d\}} P_{N,p}[\{ \tilde{w} \in W_{N,p} : \tilde{w}(j) = w(j), \ j = 0, 1, 2, \cdots, n \}],
\]
which proves that the right-hand side of (17) gives the same value for all $N$ satisfying (15).

We next extend $\tilde{P}_n$, defined in (17) on the cylinder sets $C_n(w)$, to a probability measure. Let $\mathcal{F}_n$ be the $\sigma$-algebra on $W(\infty)$ generated by the cylinder sets $C_n(w)$ i.e., a family of sets which are determined by the first $n$ steps of the paths in $W(\infty)$. We extend $\tilde{P}_n$ to $\mathcal{F}_n$ by
\[
(18) \quad \tilde{P}_n[V] = \sum_{w \in W(n); C_n(w) \subseteq V} \tilde{P}_n[C_n(w)], \ V \in \mathcal{F}_n.
\]
To prove that $\tilde{P}_n$ is a probability measure, it is sufficient to prove $\tilde{P}_n[W(\infty)] = 1$. Let $N$ be a positive integer satisfying $2^N \geq n$. If $w' \in W_N$ then $L(w') \geq 2^N (\geq n)$, hence there exists a unique $w \in W(n)$ satisfying $w'(j) = w(j), \ j = 0, 1, 2, \cdots, n$. Using also (17), we therefore have
\[
\tilde{P}_n[W(\infty)] = \sum_{w \in W(n)} \tilde{P}_n[C_n(w)] = 1.
\]
Lastly, we note that it is a standard argument of the extension theorem that if \( \tilde{P}_n, n \in \mathbb{N} \), satisfies the consistency condition
\[
\tilde{P}_{n+1}[\mathcal{C}_n(w)] = \tilde{P}_n[\mathcal{C}_n(w)], \quad w \in W(n), \quad n = 1, 2, \ldots,
\]
then there exists a probability measure \( P^u \) on \( (W(\infty), \mathcal{F}) \) satisfying (14) for all \( n \in \mathbb{N} \) and \( w \in W(n) \).

To prove the consistency condition (19), let \( n \in \mathbb{N} \) and \( w \in W(n) \). Note that \( \mathcal{C}_n(w) \in \mathcal{F}_n \subset \mathcal{F}_{n+1} \). If \( 2^N \geq n + 1 \) then (18), and (17) imply
\[
\tilde{P}_{n+1}[\mathcal{C}_n(w)] = \sum_{w'' \in W(n+1)} \tilde{P}_{n+1}[\mathcal{C}_{n+1}(w'')]
\]
\[
= \frac{1}{4} \sum_{p \in \{a, b, c, d\}} \sum_{w'' \in W(n+1)} P_{N,p}[\{w' \in W_{N,p} : w'(j) = w''(j), j = 0, 1, 2, \ldots, n + 1\}]
\]
\[
= \frac{1}{4} \sum_{p \in \{a, b, c, d\}} P_{N,p}[\{w' \in W_{N,p} : w'(j) = w(j), j = 0, 1, 2, \ldots, n\}] = \tilde{P}_n[\mathcal{C}_n(w)].
\]

\[\square\]

**Corollary 7** If \( N \in \mathbb{N} \) and \( w \in W_N \), then
\[
P^u[\{w' \in W(\infty) : w'(j) = w(j), j = 0, 1, 2, \ldots, L(w)\}] = \frac{1}{4} \sum_{p \in \{a, b, c, d\}} P_{N,p}^u[\{w\}].
\]

**Proof.** Put \( n = L(w) \). Then the definition of \( W_N \) implies (15), hence by Theorem 5 and Proposition 6 we have the statement. \[\square\]

### 4 Displacement exponents.

In this section, we prove the following.

**Theorem 8 (Displacement exponent)** Let \( \gamma_u = \frac{\log 2}{\log \lambda_u}, u \geq 0 \), where \( \lambda_u \) is a continuous function of \( u \) defined in Proposition 1. Then, for any \( s > 0 \),
\[
\lim_{n \to \infty} (\log n)^{-1} \log E^u[|w(n)|^s] = s\gamma_u,
\]
where \(| \cdot |\) denotes the Euclidean metric.

Our proof below implies an additional statement on the correction to the `leading term' \( \log E[|w(n)|^s] \sim s\gamma_u \log n \) in Theorem 8. See (37) and (38) for details.

Let us study the location of the walk after \( n \)-steps. Define for \( w \in W(\infty) \cup \bigcup_{k \geq n} W(k) \)
\[
D_n(w) = \min\{ M \geq 0 : |w(i)| \leq 2^M, 0 \leq i \leq n \},
\]
and
\[
||w||_n = \max_{0 \leq i \leq n} |w(i)|.
\]

Then
\[
2^{D_n(w)-1} < ||w||_n \leq 2^{D_n(w)}
\]
holds. Let \( K(n) \) be the positive integer such that
\[
\lambda_u^{K(n)} \leq n < \lambda_u^{K(n)+1}.
\]
Proposition 9 (Long-path estimate) There exist positive constants $C_1 = C_1(u)$ and $C_2 = C_2(u)$ such that for any positive integers $n$ and $M$, $P^n[ D_n(w) \geq K(n) + M ] \leq C_2 \varepsilon^{-C_2 n^2}.$

To prove this proposition, we prepare a few lemmas. In the following we fix $u \geq 0$ arbitrarily and simply write $\Phi_N(\cdot, u) = \Phi_N(\cdot)$, $\Phi_1(\cdot, u) = \Phi(\cdot)$ and $\lambda_u = \lambda$.

Lemma 10 If $x < x_u$, then there exist positive constants $C_3 = C_3(u, x)$ and $C_4 = C_4(u, x)$ such that $\Phi_N(x) < C_4 e^{-C_2 n^2}$ for all $N \in \mathbb{N}$.

Proof. We use the fact that $\Phi(x)$ is a power series of $x$ without constant and linear terms, with non-negative coefficients. We can easily see that for $x < x_u$, $\{\Phi_N(x)\}_{N=1,2,\ldots}$ is a decreasing sequence and since $0$ is the only fixed point of $\Phi$ in $[0, x_u)$, we see that $\Phi_N(x, u) \to 0$ as $N \to \infty$. We also see

$$\Phi_{N+1}(x) = \Phi(\Phi_N(x)) = \Phi_N(x)^2 P(\Phi_N(x)),$$

where $P$ is expressed as a power series with non-negative coefficients. This combined with $P(\Phi_N(x)) < P(x_u) = 1/x_u$ implies

$$2^{-(N+1)} \{ \log \Phi_{N+1}(x) + \log 1/x_u \} < 2^{-N} \{ \log \Phi_N(x) + \log 1/x_u \}.$$

By repeated use of this inequality, we have

$$\limsup_{N \to \infty} 2^{-N} \log \Phi_N(x) = \limsup_{N \to \infty} 2^{-N} \{ \log \Phi_N(x) + \log 1/x_u \} \leq \log \frac{x}{x_u} = -C_3 < 0.$$

This implies that there is an $N_0 \in \mathbb{N}$ such that $\Phi_N(x) \leq e^{-C_3 n^2}$ for any $N > N_0$. Taking $C_4$ large enough, we have the statement. \hfill \Box

Lemma 11 For any $\delta > 0$, there exist positive constants $C_3' = C_3'(u, \delta)$ and $C_4' = C_4'(u, \delta)$ such that $\Phi_{N+M}(x_u^{1+\delta} - N) \leq C_4' e^{-C_3' n^2}$, for any $N, M \in \mathbb{N}$.

Proof. Since $\Phi_{N+M}(x_u^{1+\delta} - N) = \Phi_M(\Phi_N(x_u^{1+\delta} - N))$, the statement is proved from Lemma 10 if we show that there exists a positive constant $C_3$ such that

$$\Phi_N(x_u^{1+\delta} - N) < x_u^{1+\delta} - \varepsilon$$

for all $N \in \mathbb{N}$. Let $\tilde{g}_N(t) = E[e^{-t N^\lambda S_1^N}] = \frac{1}{x_u} \Phi_N(x_u e^{-\lambda N})$, $t \geq 0$, be the Laplace transform of $\lambda N S_1^N$. Note that

$$\Phi_N(x_u^{1+\delta} - N) = x_u \tilde{g}_N(-\delta \log x_u).$$

Proposition 3 and Proposition 4 imply that $\tilde{g}_N(t)$ converges to $g(t) = E[e^{-t S^*}]$ as $N \to \infty$. Since $P[S^* > 0] = 1$, we have $g(t) < 1$ for any $t > 0$. Thus there exist an $\varepsilon' > 0$ and $N_1 \in \mathbb{N}$ such that $\Phi_N(x_u^{1+\delta} - N) < x_u^{1+\delta} - \varepsilon'$ for all $N > N_1$. Since it holds that $\Phi_N(x_u^{1+\delta} - N) < x_u$ also for $N = 1, \cdots, N_1$, there exists $\varepsilon > 0$ satisfying (23). \hfill \Box

Proof of Proposition 9. The equations (21) and (22) imply

$$P^n[ D_n(w) \geq K(n) + M ] \leq P^n[ S_1^{K(n)+M-1} < n ] \leq P^n[ S_1^{K(n)+M-1} < \lambda K(n)+1 ].$$

Corollary 7 and (12) imply that, if $0 \leq M - 2 \leq J$,

$$P^n[ S_1^{J} < \lambda^{J-M+2} ] = \frac{1}{4} \sum_{p \in \{a,b,c,d\}} P^n_{J,p}[ S_1^{J} < \lambda^{J-M+2} ] = P^n_{J,a}[ S_1^{J} < \lambda^{J-M+2} ] = \frac{1}{x_u} \Phi_{J,a}(x_u^{1+\lambda^{-(J-M+2)})},$$

where we used $S_1^{J} = L(w)$ for $w \in W_{J,a}$ and $x_u^{L(w)(1+1/L(w))} \leq (x_u^{1+\lambda^{-(J-M+2)})L(w})$. This combined with Lemma 11 and (25) leads to $P^n[ D_n(w) \geq K(n) + M ] \leq C_2 e^{-C_2 n^2}.$ \hfill \Box
Proposition 12 (Short-path estimate) There exists a positive constant $C_5 = C_5(u)$ such that for any positive integers $n$ and $M$ satisfying $M < K(n)$,

$$P^u[D_n(w) < K(n) - M] \leq \frac{1}{x_u} e^{-C_5 \lambda^M}.$$ 

Proof. Put $N = K(n) - M$. Taylor’s theorem implies, for $|z| \leq 1$, $|\Phi(x_u + z) - x_u| \leq \lambda |z|(1 + b|z|)$, where $b = \frac{1}{2\lambda} \max_{|y| \leq 1} |\Phi''(x_u + y)|$. Let $a$ be a positive number such that $a \cdot \prod_{k=0}^{\infty} (1 + b\lambda^{-k}) \leq 1$. Then by induction we can show that for $|z| \leq a\lambda^{-N}$ and any $K \leq N$,

$$|\Phi_K(x_u + z) - x_u| \leq \lambda^K |z| \prod_{\ell=0}^{K-1} (1 + b\lambda^{-(N-\ell)}) \leq \frac{\lambda^K |z|}{a}.$$ 

Since $x_u < 1$, we can choose $0 < C_5 < \frac{1}{2}$ so that $(1 + \frac{2C_5}{a})x_u \leq 1$. Since $e^{x/2} \leq 1 + x$ for $0 \leq x \leq 1$, (26) implies

$$\Phi_N(x_u e^{\lambda^{-N}C_5}) \leq \Phi_N(x_u (1 + 2C_5\lambda^{-N})) \leq x_u(1 + \frac{2C_5}{a}) \leq 1.$$ 

Thus we have

$$E_N^u[e^{\lambda^{-N}S_1^N C_5}] = \frac{x_u}{x_u} \Phi_N(x_u e^{\lambda^{-N}C_5}) \leq \frac{1}{x_u}.$$ 

Using Chebyshev’s inequality, we obtain

$$P^u_{N,a}[\frac{S_1^N}{\lambda^N} \geq \lambda^M] \leq \frac{1}{x_u} e^{-C_5 \lambda^M}.$$ 

Note that $D_n(w) < N$ implies that $S_1^N > n$. Therefore

$$P^u[D_n(w) < N] = \frac{1}{4} \sum_{q \in \{a,b,c,d\}} P^u_{N+1,q}[D_n(w) < N] = P^u_{N,a}[D_n(w) < N] \leq P^u_{N,a}[S_1^N > n].$$ 

This combined with (22) and (27) implies the statement. \qed

We move on to the reflection argument. The exponent $\gamma_u$ in Theorem 8 takes the same value as the one that governs the short-time speed of the corresponding continuum limit process, $E[|X(t)|^t] \sim t^{\gamma_u}$, $t \to 0$, obtained in [3]. The reason is that both exponents are derived from the same renormalization group analysis. However, to relate the renormalization group results to the asymptotic behaviors of the walks, we need different methods, as may be easily anticipated from the fact that the continuum limit processes have self-similarity, while the walks (discrete chains) do not. One of the main tools here is a somewhat complicated use of a reflection principle, which we will explain in detail.

In the reflection argument, we split paths into parts, hence we have to consider paths starting from points other than $O$. Let

$$W = \bigcup_{n=1}^{\infty} \{(w(0), w(1), \ldots, w(n)) : w(i) \in G_0, |w(i+1) - w(i)| = 1, \overline{w(i)w(i+1)} \in F_0, i \in \{0, 1, \ldots, n-1\}\}.$$ 

Namely, $W$ is a set of finite-length paths whose starting points are not fixed at $O$. We extend the definitions of the reversing number $N_K(w)$ and the returning number $M_K(w)$ so that they hold also for any $w \in W$. Define

$$N_K(w) = \sum_{\ell=0}^{L(Q_{K+1}w)+1} N_K(\ell)(w)$$ 

and

$$M_K(w) = \sum_{\ell=1}^{L(Q_{K+1}w)+1} M_K(\ell)(w),$$

10
where, for $\ell = 1, \ldots, L(Q_{K+1}w)$, $N_K(\ell)$ and $M_K(\ell)$ are defined by (1) and (2), and the term for $\ell = 0$ is counted only if $T_0^{K+1}(Q_Kw) > 1$, with

$$N_K(0)(w) = \sharp \{ i \in \mathbb{Z}_+: 0 < i < T_0^{K+1}(Q_Kw) : (Q_Kw)(i-1)(Q_Kw)(i) \cdot (Q_Kw)(i)(Q_Kw)(i+1) < 0 \},$$

and the term for $\ell = L(Q_{K+1}w) + 1$ is counted only if $(Q_Kw)(L(Q_Kw)) \not\in G_{K+1}$, with

$$N_K(L(Q_{K+1}w) + 1)(w) = \sharp \{ i \in \mathbb{Z}_+: T_{L(Q_{K+1}w)}^K(Q_Kw) < i \leq L(Q_Kw) - 1 : (Q_Kw)(i-1)(Q_Kw)(i) \cdot (Q_Kw)(i)(Q_Kw)(i+1) < 0, (Q_Kw)(i) \neq (Q_Kw)(T_{L(Q_{K+1}w)}^K(Q_Kw)) \}.$$ 

and

$$M_K(L(Q_{K+1}w) + 1)(w) = \sharp \{ i \in \mathbb{Z}_+: T_{L(Q_{K+1}w)}^K(Q_Kw) < i \leq L(Q_Kw) : (Q_Kw)(i) = (Q_Kw)(T_{L(Q_{K+1}w)}^K(Q_Kw)) \}.$$ 

The definition of $f_N(w)$ given by (3) is unchanged.

Let $w \in W_N$. Consider splitting $w$ into two parts at a time $t < L(w)$. Let

$$w_1(i) = w(i), \quad 0 \leq i \leq t, \quad \text{and} \quad w_2(i) = w(t+i), \quad 0 \leq i \leq L(w) - t.$$ 

Then

$$(28) \quad L(w_1) = t, \quad L(w_2) = L(w) - t.$$ 

Note that for $K \leq N$,

$$T_0^K(w_2) = \inf \{ i \geq 0 : w_2(i) \in G_K \} = \inf \{ i \geq 0 : w(t+i) \in G_K \}.$$ 

**Proposition 13 (Path splitting)** Let $w \in W_N$. Assume that $w$ is split into two parts at some time $t < L(w)$.

1. If $w(t) \in G_M \setminus G_{M+1}$ for some $M < N$, then

$$f_N(w) \leq f_N(w_1) \cdot f_N(w_2) \leq u^{-3(N-M)} f_N(w) \quad \text{for} \quad 0 \leq u \leq 1,$n

$$u^{-3(N-M)} f_N(w) \leq f_N(w_1) \cdot f_N(w_2) \leq f_N(w) \quad \text{for} \quad u > 1,$$

$$L(w) = L(w_1) + L(w_2).$$

2. If $w(t) = O$, then

$$f_N(w) = f_N(w_1) \cdot f_N(w_2),$$

$$L(w) = L(w_1) + L(w_2).$$

**Proof.** (1) First consider $N_K(w)$ with $M \leq K \leq N - 1$. There is an integer $\ell(K)$ such that $T_{\ell(K)-1}^K(w) \leq t < T_{\ell(K)}^K(w)$. $w_2(T_0^K(w_2))$ coincides either with $w(T_{\ell(K)-1}^K(w))$ or $w(T_{\ell(K)-1}^K(w))$. When we count sharp turns and U-turns of $w_1$ and $w_2$, at most two turns of $(Q_Kw)(i)$ at $i = \ell(K) - 1$ or $\ell(K)$ may elude the counting (see Fig. 1). Thus

$$N_K(w) - 2 \leq N_K(w_1) + N_K(w_2) \leq N_K(w).$$

As for $M_K(w)$ with $M \leq K \leq N - 1$, there is an integer $\ell'(K+1)$ such that $T_{\ell'(K+1)-1}^K(w) < t < T_{\ell'(K+1)}^K(w)$. $w_2(T_0^{K+1}(w_2))$ coincides either with $w(T_{\ell'(K+1)-1}^K(w))$ or $w(T_{\ell'(K+1)-1}^K(w))$. In the latter case, the first return of $Q_Kw$ to $w(T_{\ell'(K+1)-1}^K(w))$ after $t$ eludes the counting in $M_K(w_2)$. Thus

$$M_K(w) - 1 \leq M_K(w_1) + M_K(w_2) \leq M_K(w).$$

Thus, for $M \leq K$ we have

$$(29) \quad N_K(w) + M_K(w) - 3 \leq N_K(w_1) + M_K(w_1) + N_K(w_2) + M_K(w_2) \leq N_K(w) + M_K(w).$$

11
For \( N_K(w) \) and \( M_K(w) \) with \( 1 \leq K < M \), from the fact that \( w_2(0) \in G_{K+1} \subset G_M \), it holds that

\[
N_K(w) = N_K(w_1) + N_K(w_2),
\]

and

\[
M_K(w) = M_K(w_1) + M_K(w_2).
\]

(29), (31) and (30) combined with (3) prove the proposition. (2) is immediate if we note that splitting at \( O \) does not affect \( N_K(w) \) or \( M_K(w) \). \( \square \)

**Proposition 14 (Reflection principle)** There exists \( C_6 = C_6(u) > 0 \) such that for any \( n \in \mathbb{N} \) and \( s > 0 \)

\[
C_6 \ E^w[ 2^D_n(w)^s, \ |w(n)| \geq 2^{D_n(w-2)} ] \geq E^w[ 2^D_n(w)^s, \ |w(n)| < 2^{D_n(w-2)} ]
\]

*Proof.* First, fix arbitrarily \( N \in \mathbb{N} \) and condition on \( \{ D_n(w) = N \} \). Then it is enough to study the behavior of paths within \( F_{N+1}'' \).

For \( w \in W(n) \) such that \( D_n(w) = N \), let \( T(n,A_{N-2}) = \sup\{i < n : w(i) \in A_{N-2}\} \), where \( A_M = \{a_M,b_M,c_M,d_M\} \). Define

\[
U_N(z) = \{w \in W(n) : D_n(w) = N, |w(n)| < 2^{N-2}, w(T(n,A_{N-2})) = z\},
\]

\[
V_N(z) = \{w \in W(n) : D_n(w) = N, |w(n)| \geq 2^{N-2}, w(T(n,A_{N-2})) = z\}, \quad z \in A_{N-2}.
\]

For \( w \in U_N(b_{N-2}) \), let us denote by \( w_R \) the \( n \)-step path obtained from \( w \) by reflecting the part \( \{w(i) : T(n,A_{N-2}) < i \leq n\} \) with respect to a line parallel to the y-axis that passes \( b_{N-2} \) (see Fig. 2). This mapping is an injection from \( U_N(b_{N-2}) \) to \( V_N(b_{N-2}) \). Also for the case that \( z \in \{a_{N-2},c_{N-2},d_{N-2}\} \), we can define an injection from \( U_N(z) \) to \( V_N(z) \) in the following way. For \( w \in U_N(z) \), we first reflect the part \( \{w(i) : T(n,A_{N-2}) < i \leq n\} \) at \( z \), and if the reflected path leaks out of \( F_0 \), then reflect the leaking part appropriately so that it lands on \( F_0 \) (see Fig. 3). We denote the reflected path for the cases
Figure 2:

$z \in \{a_{N-2}, c_{N-2}, d_{N-2}\} \text{ also by } w_R.$

For $\tilde{w} \in U_N(z) \cup V_N(z)$, define

$$p_{N+1}(\tilde{w}) = \sum_{w' \in W_{N+1}} f_{N+1}(w') x^{L(w')-1},$$

where the summation is taken over $w' \in W_{N+1}$ with $w'(i) = \tilde{w}(i)$ for $i = 0, 1, \cdots, n$. We claim that there exists a positive constant $M_3$ that depends only on $u$ such that

$$p_{N+1}(w_R) \geq M_3 p_{N+1}(w) \quad (32)$$

holds for all $w \in U_N(z)$, $z \in A_{N-2}$ and $N \in \mathbb{N}$.

With (32), the proposition is proved as follows. Let

$$U_N = \{ w \in W_{N+1} : D_n(w) = N, \ |w(n)| < 2^{N-2} \},$$

$$V_N = \{ w \in W_{N+1} : D_n(w) = N, \ |w(n)| \geq 2^{N-2} \}. $$

Corollary 7 and (32) imply

$$E[u][2^{D_n}, |w(n)| < 2^{D_n-2}] = \sum_{N=1}^{\infty} 2^{Ns} P^u[ D_n(w) = N, \ |w(n)| < 2^{N-2} ]$$

$$= \sum_{N=1}^{\infty} 2^{Ns} \frac{1}{4} \sum_{p \in \{a,b,c,d\}} \sum_{w \in U_N \cap W_{N+1,p}} \sum_{P_{N+1,p}[\{w\}]}$$

$$\leq \sum_{N=1}^{\infty} 2^{Ns} \frac{1}{4M_3} \sum_{p \in \{a,b,c,d\}} \sum_{w \in V_N \cap W_{N+1,p}} \sum_{P_{N+1,p}[\{w\}]}$$
This implies the statement, with \( C_6 = \frac{1}{M_3} \).

It remains to prove (32). We prove for the case \( w \in U_N(b_{N-2}) \) and \( 0 \leq u \leq 1 \). The other cases can be proved in a similar manner. Put \( e_M = \frac{a_{M+1} + b_{M+1}}{2} \), \( M \in \mathbb{Z}_+ \). For a path \( w \in U_N(b_{N-2}) \), \( w(n) \) can lie either in \( \Delta a_{N-2}b_{N-2} \) or in \( \Delta o_{N-2}a_{N-2} \). Let us consider the first case. Note that \( w_R(n) \) lies in \( \Delta a_{N-2}b_{N-2} \). We will prepare some inequalities relating \( w \) and \( w_R \). For \( w' \in \bigcup_{k \geq n} W(k) \), put \( T(n+,G_M) = \inf \{ i \geq n : w'(i) \in G_M \}, M \in \mathbb{N} \). Note that if \( w'(n) \in \Delta a_{N-2}b_{N-2} \), then \( w'(T(n+,G_{N-2})) \in \{a_{N-2},b_{N-2},O\} \) and if \( w'(n) \in \Delta b_{N-2}c_{N-2} \), then \( w'(T(n+,G_{N-2})) \in \{c_{N-2},b_{N-2},b_{N-1}\} \). We will extend \( w \) and \( w_R \) up to time \( T(n+,G_{N-2}) \). To this end, we define for \( \tilde{w} \in U_N(b_{N-2}) \cup V_N(b_{N-2}) \)

\[
H(z)[\tilde{w}] = \sum_{i=0}^{L(w'-1)} f_{N+1}(w') x_u^{L(w')-1}, z \in G_{N-2},
\]

where the summation is taken over \( w' \in \bigcup_{k \geq n} W(k) \) satisfying \( w'(i) = \tilde{w}(i) \) for \( i = 0, \ldots, n \), and \( w'(L(w')) = w'(T(n+,G_{N-2})) = z \).
Taking into account the possibility that $w_R$ makes a $2N^{-2}$-scale sharp turn at the reflection point $b_{N-2}$ while $w$ does not, we have

$$H(e_{N-2})[w_R] \geq uH(a_{N-2})[w],$$

(33)

$$H(b_{N-2})[w_R] \geq uH(b_{N-2})[w],$$

(34)

$$H(b_{N-1})[w_R] \geq uH(O)[w].$$

(35)

Next we introduce two quantities $\Xi$ and $\Xi'$. Let $W_M^a = \{w \in W : w(0) = a_M, L(w) = T_{AM}(w)\}, M \in \mathbb{Z}_+$, and $\Xi = \sum_{w \in W_M^a} f_1(w)x_u(w)$. We will show that for any $M \in \mathbb{N}$, $\sum_{w \in W_M^a} f_{M+1}(w)x_u(w) = \Xi$ holds.

Note that if $w \in W_M^a$, then $2^{-M}Q_M w \in W_0^a$. We split $w$ into segments $w_i$ such that $w_i(t) = w(T_{M_i}^{-1}(w) + t), 0 \leq t \leq T_{M_i}^{-1}(w) - T_{M_{i-1}}^{-1}(w), i = 1, \ldots, L(2^{-M}Q_M w)$, and apply (30) and (31). Noting that each $w_i$ can be identified, via reflection, with a path in $W_M,a$, we have

$$\sum_{w \in W_M^a} f_{M+1}(w)x_u(w) = \sum_{w \in W_M^a} \sum_{w_i \in W_M,a} x_u(w_i) \prod_{i=1}^{M-1} u^{N_K(w_i) + M_K(w_i)} u^{N_M(w_i) + M_M(w_i)} = \Xi.$$

Moreover, symmetry arguments imply that if the summation is taken over paths starting at any other point in $A_M$, instead of $a_M$, the corresponding value is equal to $\Xi$. Let $W_M^a = \{w \in W : w(0) = a_M, L(w) = T_{AM}(w)\}$, and $\Xi' = \sum_{w \in W_M^a} f_1(w)x_u(w)$. In a similar manner to the above argument, we see that for any $M \in \mathbb{N}$, it holds that $\sum_{w \in W_M^a} f_{M+1}(w)x_u(w) = \Xi'$.

Now we are ready to prove (32). Let $w \in U_N(b_{N-2})$. We devide the path $w'$ in the summation into segments by splitting at $T(n+G_{N-2})$, and if necessary, also at $T(n+G_{N-1})$ and at $T(n+G_N)$. Then Proposition 13 gives,

$$p_{N+1}(w) \leq (H(a_{N-2})[w] + H(b_{N-2})[w]) \Xi^3 + H(O)[w] : 4x_u,$$

where we used $\Phi_M(x_u,u) = x_u$. Splitting $w_R$ at $T(n+G_{N-2})$, and, if necessary, also at $T(n+G_{N-1})$ and $T(n+G_N)$, we have from Proposition 13 and (33) – (35),

$$p_{N+1}(w_R) \geq u^{9+6+3}(H(e_{N-2})[w_R] \Xi^2 + H(b_{N-2})[w_R] \Xi^3) + u^9(H(b_{N-1})[w_R] \Xi^2$$

$$\geq u^{19}(H(a_{N-2})[w] \Xi^2 + H(b_{N-2})[w] \Xi^3) + u^{10}H(O)[w] \Xi^2$$

$$\geq u^{19}M_1((H(a_{N-2})[w] + H(b_{N-2})[w]) \Xi^3 + 4H(O)[w]x_u)$$

$$\geq u^{19}M_{1PN+1}(w),$$

where we put $M_1 = \min\{1, \frac{\Xi}{\Xi}, \frac{\Xi^2}{4x_u}\} > 0$.

The case $w(n) \in \triangle_{NCN-2dN-2}$ can be handled in the same way to give $p_{N+1}(w_R) \geq u^{13}M_2PN_{1+1}(w)$, where $M_2$ is a positive constant depending only on $u$. Thus (32) holds with $M_3 = \min\{u^{10}M_1, u^{13}M_2\} > 0$. \hfill \Box
Let \( C_0 = \frac{1}{1 + C_0} \). Proposition 14 implies
\[
E^u[ |w(n)|^s ] \geq E^u[ 2^{(D_n(w)-2)s} |w(n)| \geq 2^{D_n(w)-2} ] \\
\geq \frac{1}{1 + C_0} E^u[ 2^{(D_n(w)-2)s} ] = 2^{-2s} C_0 E^u[ 2^{D_n(w)s} ] ,
\]
which, with the definitions of \(|w|_n\) and \(D_n(w)\), further implies

**Proposition 15** \( 2^{-2k} C_0 E^u[ 2^{D_n(w)s} ] \leq E^u[ |w(n)|^s ] \leq E^u[ |w|_n^s ] \leq E^u[ 2^{D_n(w)s} ] \).

**Proof of Theorem 8.** Assume \( \beta > 0 \).

\[
E^u[ |w|_n^s ] = E^u[ |w|_n^s , |w|_n < (\log n)^{3/2} n^\gamma ] + E^u[ |w|_n^s , |w|_n \geq (\log n)^{3/2} n^\gamma ] \leq (\log n)^{3/2} n^\gamma P^u[|w|_n \geq (\log n)^{3/2} n^\gamma ] ,
\]
where we used \(|w|_n| \leq n\). Also, (21), (22), and \( \gamma = \log 2 / \log \lambda \) imply
\[
P^u[|w|_n \geq (\log n)^{3/2} n^\gamma ] \leq P^u[D_n(w) \geq (\log n)^{3/2} n^\gamma ] \leq \frac{\beta \log \log n}{\log 2} + \frac{\log n}{\log \lambda} + K(n) \leq C_2 \exp(-C_1(\log n)^\beta) ,
\]
where in the last inequality Proposition 9 was used. This combined with (36) gives
\[
(\log n)^{-\alpha} n^{-\gamma} E^u[ |w|_n^s ] \leq 1 + (\log n)^{-\alpha} n^{(1-\gamma)} C_2 \exp(-C_1(\log n)^\beta) \leq C_2(\log n)^{-\alpha} n^{-\gamma} ,
\]
for any large \( n \) such that \( C_1(\log n)^\beta \geq \alpha \log n \). Thus
\[
\limsup_{n \to \infty} (\log n)^{-\alpha} n^{-\gamma} E^u[ |w|_n^s ] \leq 1 .
\]

On the other hand, combining (21), (22) and Proposition 12 in a similar way to the above argument, we see that for any \( \alpha > 0 \) there exists a constant \( C' > 0 \) such that
\[
E^u[ |w|_n^s ] \geq \{ (\log n)^{-\alpha} n^\gamma \} \{ 1 - P^u[|w|_n < (\log n)^{-\alpha} n^\gamma ] \} \geq \{ (\log n)^{-\alpha} n^\gamma \} \{ 1 - \frac{1}{x_u} \exp(-C'(\log n)^{\alpha/\gamma}) \} .
\]
Thus
\[
\liminf_{n \to \infty} (\log n)^{\alpha} n^{-\gamma} E^u[ |w|_n^s ] \geq 1 .
\] (37) and (38) imply \( \lim_{n \to \infty} (\log n)^{-1} \log E^u[ |w|_n^s ] = s\gamma \), which combined with Proposition 15, further implies the assertion of the theorem. \( \square \)
